Abstract

The collaborative development methods pioneered by the open source software community offer a way to create lessons that are open, accessible, and sustainable. This paper presents ten simple rules for doing this drawn from our experience with several successful projects.

Author summary

Lessons take significant effort to build and maintain. We have found that the collaborative development methods pioneered by the open source software community are an effective, economical way to create and sustain lessons that can be used by large numbers of people in a wide variety of contexts. The ten simple rules outlined in this paper summarize the best practices that we have helped evolve in several successful open education projects aimed at researchers and research librarians in a wide range of disciplines.

Introduction

Lessons take significant effort to build and even more to maintain. Most academics do this work on their own, but leveraging a community approach can make educational resource development more sustainable, robust, and responsive. Treating lessons as a community resource to be updated, adapted, and improved incrementally, can free up valuable time while increasing quality.

Despite the success of openness in software development and the curation of Wikipedia, it is an uncommon approach in academic settings. Each year, thousands of university lecturers teach subjects ranging from first year biology, to graduate-level courses in Indian film. Some use textbooks written by one or a few authors, but beyond that, they develop and maintain their course materials in isolation. This is curious given that research depends critically on sharing, and that most researchers complain about

how much time teaching takes away from research, but the sociology and psychology behind this blind spot are out of the scope of this paper.

The authors have many years of experience with community-developed lessons in the context of research computing in the sciences and humanities through organizations like Software Carpentry and Programming Historian. Software Carpentry was founded in 1998 to teach scientists basic computing skills, and has since spawned two sibling organizations called Data Carpentry and Library Carpentry. Programming Historian was founded in 2008, and has evolved into a collaboratively-edited site providing lessons to humanities scholars. Their guiding principles are that lessons should be:

1. open and easily accessible, and
2. continually maintained, refined, and improved by a community of contributors.

All open education projects satisfy the first criterion by definition, but few satisfy the second. While their lessons are occasionally updated by a small team (as happens when a new edition of a book is edited and published), this is not the same as continuous improvement by a large community of contributors. The ten simple rules that follow summarize what we have learned about doing that as maintainers, editors, and reviewers of lessons used by tens of thousands of people (Fig. 1, 2).

Acknowledgments

We are grateful to everyone who provided feedback on this paper, including James Baker, Nathan Moore, Pariksheet Nanda, Tom Pollard, Byron Smith, and Andrew Walker. We are also grateful to the hundreds of people who have contributed to Programming Historian, Data Carpentry, Software Carpentry, and Library Carpentry over many years.

1 Clarify your audience

The first requirement for building lessons together is to know who they are being built for. “Archaeology students” is far too vague: are you and your collaborators thinking of first-year students who need an introduction to the field, graduate students who intend to specialize in the sub-discipline which is the lesson’s focus, or someone in between? If different contributors believe different things about prerequisite knowledge, equipment or software required, or how much time learners will have, they will find it difficult to work together.

Instead of starting with learning objectives (Rule 3), it can be helpful to write *learner profiles* to clarify the learner’s general background, what they already know, what *they* think they want to do, how the material will help them, and any special needs they might have. This technique is borrowed from user interface design, and a typical learner profile is presented in Box 1.

2 Make lessons modular

Every instructor’s needs are different, so build small chunks that can be re-purposed in many ways. A university lecturer in meteorology, for instance, might construct a course for their students by bringing together lessons on differential equations, fluid mechanics, and absorption spectroscopy. Creating courses this way shifts the instructor’s burden from writing to finding and synthesizing, which are easier if lessons clearly define what they cover (Rule 1), and if lessons have been designed by people with a shared world-view (Rule 3).

One way to achieve this is to take existing courses and break them down into smaller, single-purpose modules (a change which has pedagogical and administrative advantages in its own right). When this is done, these modules can be made more discoverable by referencing specific points in the model curricula promulgated by many professional societies (e.g., as learning objectives). Smaller modules are also more approachable for new contributors (Rule 4).

3 Teach best practices for lesson development

Decades of pedagogical research has yielded many insights into how best to build and deliver lessons [1]. Unfortunately, many college and university faculty have little or no training in education [11], so this knowledge is rarely applied in the classroom.

Our experience is that even a brief introduction to a few key practices helps collaborative lesson development. If people have a shared understanding of how lessons should be developed, it is easier for them to work together. Less obviously, if people have a shared model of how lessons will be *used*, they are more likely to build reusable material. Finally, teaching people how to teach is a great way to introduce them to each other and build community.

One popular lesson development methodology is presented in [2]. When this is used, lessons are built by:

1. identifying learning objectives,
2. creating *summative assessments* to determine whether those objectives have been met,
3. designing *formative assessments* to gauge learners' progress and give them a chance to practice key skills,
4. putting those formative assessments in order,
5. and only then writing lessons to connect each to the next.

This method is effective in its own right, but its greatest benefit is that it gives everyone a framework for collaboration.

An example of how to teach these practices is Software Carpentry's instructor training program. First offered in 2012, is now a two-day course delivered both in-person and online [3–5]. This program teaches good pedagogical practices, and introduces everyone who takes it to who Software Carpentry's lessons are for, how they are delivered, and how they are maintained. Largely as a result of this training, several hundred people per year now contribute to Software Carpentry's lessons.

4 Encourage and empower contributors

Making the process for contributing to a lesson simple and transparent is the key to receiving contributions. Licensing, code of conduct, governance, and the review and publication process must all be explicit rather than implicit to lower the social barriers to contribution.

Tools can help, especially if they allow proposed changes to be viewed and discussed prior to their incorporation into the lessons. (In software development this is known as "pre-merge review".) However, some tools that are popular in open source software development have considerable up-front learning costs. Portals like GitHub, for example, support everything that open lesson development needs, but require contributors to use Git, which has a notoriously steep learning curve [10].

Complicating matters further, some file formats make collaboration easier or more difficult. Despite their ubiquity, open source version control systems do not directly support review or merge of Microsoft Office or LibreOffice file formats, which raises an additional burden for newcomers [12]. Programmers may look down on Google Docs and wikis for their lack of pre-merge review and other capabilities, but their low barrier to entry make them more welcoming to newcomers.

The best way to choose tools for managing lessons is to ask potential contributors what they are comfortable with rather than requiring *them* to come to *you*. Remember also that contributing to a lesson is probably not their top priority, and look for ways to reduce their cognitive load. For example, threaded discussion forums can improve the signal-to-noise ratio by reducing long reply-all email exchanges. Several open frameworks are available to facilitate development of new lessons, such as learnr (<https://rstudio.github.io/learnr>), Morea (<https://morea-framework.github.io>), and DataCamp's templates (<https://www.datacamp.com/teach/documentation>).

5 Build community around lessons

Software versions and dependencies are constantly changing, while the academic literature is advancing at an ever-increasing pace. As a result, what is cutting edge one year may be out of date the next and simply wrong the year after. Collaborative lesson development groups must therefore focus on creating a community in which contributors support each other rather than on relying on a small group of stewards. Authors cannot be expected to maintain continual vigilance on a lesson, but this is necessary for continual use.

A key part of doing this is to create opportunities for legitimate peripheral participation. Curating a list of small tasks that newcomers can easily tackle, encouraging them to give feedback on proposed changes, or asking them to add new exercises and tweak diagrams and references can all provide an on-ramp for people who might question their authority or ability to change the main body of a lesson. Equally, acknowledging all contributions, however small, gives new contributors an early reward for taking part.

Finally, working in the open can be great, but can also unintentionally suppress voices. Programming Historian makes an ombudsperson available for private chats and facilitation to ensure that no one is excluded.

6 Publish periodically and recognize contributions

Like software, specific versions of lessons should be published or released periodically so that learners or instructors have something stable to refer to for the duration of their use. Periodic releases also provide an opportunity for recognizing the contributions of new authors and maintainers.

Academia has only a few ways of recognizing contributions. Until these are expanded, it is important to publish lessons in ways that traditional academic systems can digest. One is to give releases DOIs supplied by providers such as Zenodo (<https://zenodo.org/>) or DataCite (<https://www.datacite.org/>). Contributors can be listed as authors and the maintainers of the lesson as editors to differentiate recognition of their contributions. Each time the lesson is published, names (and identifiers such as ORCIDs (<https://orcid.org/>)) should be gathered for all contributors.

A lesson release is a good opportunity to bring the material into a stable shape by fixing outstanding issues and merging contributions. Version control automatically maintains a list of contributors, and can also be used to track what content is in what release (e.g., using branches or tags). Lesson releases should use a consistent naming scheme; Software Carpentry has used the year and month of release (e.g., “2017.05”) in its releases [6, 7].

If lessons are being released regularly, automate the process and archive old versions in a discoverable location. Also make sure that everyone involved knows what “done” look like, i.e., which outstanding issues have to be addressed and how it has to be formatted in order for the next release to go out. A simple checklist stored with the lesson materials is good enough to start, but as time goes by, the community may want to use an issue tracking system of some sort so that work items can be assigned to specific people and then ticked off as they are completed.

7 Evaluate lessons at several scales

What people immersed in developing lessons think needs fixing can easily differ from what learners think. It is therefore critical to gather and act on feedback at several scales to check assumptions and stay on course.

Micro-scale feedback can be gathered by an instructor while teaching a particular lesson. Learners can provide feedback on everything from typographical errors and the clarity of quiz questions to the order in which topics are presented, all of which the instructor should record at the end of each class in some shared location (such as a Google Doc or GitHub issues). As well as encouraging direct verbal feedback, it’s a good idea to provide learners with a means to provide feedback anonymously during class (e.g., on small pieces of paper like sticky notes or through anonymous surveys).

Pre- and post-class surveys and interviews should be used to uncover larger issues, particularly those arising from developers not fully understanding their audience, e.g., assuming prior knowledge that learners do not have. Post-class surveys are most effective when conducted 30–90 days after class; this gives people time to reflect, so their feedback will more accurately reflect what they learned rather than how entertained they were. Clearly-stated learning objectives (Rule 3) are essential here, as they tell assessors what they should be measuring.

8 Reduce, re-use, recycle

Just as a scholar would not write a paper without a literature review, an instructor should not create a new lesson if there is an existing one they could use or contribute to. A short online search can discover if someone has written what you need, whether it is complementary to your goals, and if it can be tweaked or modified to meet your needs.

Before re-using content, make sure to check its license. Both Programming Historian and the Carpentry projects use the Creative Commons–Attribution license (<https://creativecommons.org/licenses/by/4.0/>), which allows people to share and adapt material for any purpose as long as they cite the original source. Other Creative Commons licenses may restrict commercial use and/or creation of derivative materials.

The question of licensing also arises when recycling lesson components such as images, data, figure, or code. If the license does not cover them explicitly, ask permission as you would for any other academic material.

The converse of this rule is to make the license for your lessons explicit and discoverable. For example, when lessons are published (Rule 6), make sure that that

keywords such as “CC-BY” appear in their bibliography entries and HTML page headers. 207 208

9 Link to other resources 209

Learners are unlikely to absorb everything they need to know about a topic from your lesson alone. This is partly a matter of scope—any interesting subject is too large to fit in a single lesson—but also a matter of level and direction. As Caulfield has argued [8], the best way to use the Internet is to provide a chorus of explanations that offer many angles and approaches for any given topic, each of which may be the best fit for a different set of needs. 210 211 212 213 214 215

Collaboratively-developed lessons should direct learners to these resources at strategic points. Textbooks, technical documentation, videos, web pages, threads on Quora or mailing lists: if a community or discussion forum exists for the topic, it is worth including. 216 217 218 219

Doing this is substantial work, and maintaining it is even more so, which makes building community around lessons (Rule 5) all the more important. In particular, it is vital to engage the learners as equal participants in that community: they should both be able to propose updates, corrections, and additions to lessons, and know that they are encouraged to do so (Rule 4). 220 221 222 223 224

10 You can’t please everyone 225

No single lesson can be right for every learner. Two people with no prior knowledge of a specific subject may still be able to move at different speeds because of different levels of general background knowledge. Similarly, lessons on ecology for learners in Utah and Vietnam will probably be more relatable if they use different examples. A community may therefore maintain several differently-oriented or differently-paced lessons on a single topic, just as programming languages provide several different libraries for doing the same general thing with different levels of performance and complexity. 226 227 228 229 230 231 232

Similarly, no lesson development community can serve all purposes. Some groups may prioritize rapid evolution, while others may prefer a “measure twice, cut once” approach. If there are complementary ways to explain something, or points of view that can cohabit respectfully, it may be possible to present them side by side. There are good pedagogical reasons to do this even if contributors *do not* disagree: weighing alternatives fosters higher-order thinking. 233 234 235 236 237 238

But sometimes choices must be made. The open source software community has wrestled with these issues for three decades, and has evolved some best practices to address them [9]. As discussed in Rule 4, the first step is to have a clear governance structure and a clear, permissive license. Minor disagreements should be discussed openly and respectfully. If they turn out not to be so minor after all, contributors should split off and evolve the lesson in the way they see best. (This is one of the reasons to have a permissive license.) 239 240 241 242 243 244 245

These splits rarely happen in practice. When they do, it is important to remember that we all share the same vision of better lessons, built together. 246 247

Conclusion 248

Every day, teachers all over the world spend countless hours duplicating each other’s work. These ten rules provide an alternative: adopting the model of collaborative software development to make more robust and sustainable lessons that can be 249 250 251

continually improved by those who use them. We hope that our experiences can help others teach more with more impact and less effort.

Box 1: Learner Profile

Jorge has just moved from Costa Rica to Canada to study agricultural engineering. While fluent in both Spanish and English, he has a hearing disability that sometimes makes it hard for him to understand lectures, particularly in noisy environments. Other than using Excel, Word, and the Internet, Jorge's most significant previous experience with computers is helping his sister build a WordPress site for the family business.

Jorge needs to measure properties of soil from nearby farms using a handheld device that sends text files to his computer. Right now, Jorge has to open each file in Excel, crop the first and last points, and calculate an average. This workshop will show Jorge how to write a little Python program to read the data, select the right values from each file, and calculate the required statistics.
